

Ch03 - How Git works, tracking repository

After making files, we have to track them

- `git status` → Displays the state of current directory. A newly created project isn't initialized with git.
- `git init` → Initializes an empty git repository. A new `.git` folder is auto-generated. Use `ls -a` to list all files and folders in directory.
* This folder (`.git`) is hidden.

Now `git status` will say files are untracked.

- `git add -A` → All files get added to staging area.
- `git add file.py` → Only this file is added to staging area.
- `git commit -m "Initial commit"` → All files committed !

Now `git status` says that working tree is clean which means everything is fine.

On modifying a file, `git status` says the same

- `git commit` → This opens up an active vim editor. Press 'i' then put the commit message → Esc → :wq → Enter
- `git log` → Displays a list of commits

Tagging

git can tag some particular points in repository history as important. This marks a release version.

□ `git tag -a v1.0 -m "First version of software"`

→ Creates a tag of v1.0 with this name.

You can do multiple tags.

□ `git tag` → Displays a list of tags.

□ `rm -rf .git` → Deletes .git folder. {Most dangerous command}

□ `git commit -a -m "My commit"` → Adds files to staging area and commits them.

* Untracked files do not support this command.
